

HAMILTONIAN AND LAGRANGIAN FORMALISMS OF MUTATIONS IN CLUSTER ALGEBRAS AND APPLICATION TO DILOGARITHM IDENTITIES

MICHAEL GEKHTMAN, TOMOKI NAKANISHI, AND DYLAN RUPEL

ABSTRACT. We introduce and study a Hamiltonian formalism of mutations in cluster algebras using canonical variables, where the Hamiltonian is given by the Euler dilogarithm. The corresponding Lagrangian, restricted to a certain subspace of the phase space, coincides with the Rogers dilogarithm. As an application, we show how the dilogarithm identity associated with a period of mutations in a cluster algebra arises from the Hamiltonian/Lagrangian point of view.

1. INTRODUCTION

1.1. Background and motivation. The *Euler dilogarithm*

$$(1.1) \quad \text{Li}_2(x) = \sum_{n=1}^{\infty} \frac{x^n}{n^2} = - \int_0^x \frac{\log(1-y)}{y} dy$$

appears in several areas of mathematics [Zag07]. One of the main features of this function is that it satisfies a wide variety of functional relations (*dilogarithm identities*), many of which look miraculous and mysterious. *Cluster algebras* are a class of commutative algebras introduced by Fomin and Zelevinsky [FZ02]. They originated in Lie theory but turned out to be related to several areas of mathematics.

Fock and Goncharov [FG09c] recognized that the function $\text{Li}_2(x)$ is *built into* cluster algebra theory *as a Hamiltonian*. To see this, consider the Poisson bracket introduced by [GSV03],

$$(1.2) \quad \{y_i, y_i\} = b_{ij} y_i y_j,$$

where y_1, \dots, y_n are commutative variables and $B = (b_{ij})_{i,j=1}^n$ is a skew-symmetric matrix. Then, using formula (3.4), we have

$$(1.3) \quad \{\text{Li}_2(-y_k), y_i\} = -b_{ki} \log(1+y_k) \cdot y_i.$$

This is an infinitesimal form (of the automorphism part) of the mutation of y -variables (X -variables in [FG09c]) in cluster algebras. Therefore, one may regard the function $\text{Li}_2(-y_k)$ as a Hamiltonian with continuous time variable, and the ordinary mutation is obtained as the time one flow of this Hamiltonian. This viewpoint naturally guided the authors of [FG09a, FG09b, FG09c] to quantize the cluster algebras using the *quantum dilogarithm*.

Meanwhile, there is another story which developed independently, connecting the dilogarithm and cluster algebras, where the *Rogers dilogarithm*

$$(1.4) \quad L(x) = -\frac{1}{2} \int_0^x \left\{ \frac{\log(1-y)}{y} + \frac{\log y}{1-y} \right\} dy = \text{Li}_2(x) + \frac{1}{2} \log x \log(1-x)$$

plays the central role. The function $L(x)$ is a variant of $\text{Li}_2(x)$ and it is known that many dilogarithm identities are simplified in terms of $L(x)$. In the 90's, several conjectures on dilogarithm identities for $L(x)$ were given through the study of so called *Y-systems* in integrable models of Yang-Baxter type. Later, the connection between *Y-systems* and cluster algebras was recognized [FZ03], and these dilogarithm conjectures were solved using the cluster algebraic method [Cha05, Nak11a, IIK⁺13a, IIK⁺13b] with the help of the *constancy condition* from [FS95]. Then, these results were further generalized to the following theorem [Nak11b]: *For any period in a cluster algebra, there is an associated dilogarithm identity of $L(x)$.*

It is interesting to understand how these seemingly independent appearances of the Euler and Rogers dilogarithms are intrinsically related. In [KN11] it was clarified that the dilogarithm identities in [Nak11b] are recovered through the semi-classical analysis of the corresponding *quantum dilogarithm identities*, where the Rogers dilogarithm emerges through the relation

$$(1.5) \quad L\left(\frac{x}{1+x}\right) = -\text{Li}_2(-x) - \frac{1}{2} \log x \log(1+x).$$

Furthermore, the result therein yields the following curious observation: *The relation (1.5) can be regarded as the Legendre transformation in classical mechanics, where the Euler dilogarithm is the Hamiltonian, while the Rogers dilogarithm is the Lagrangian.* However, to formulate and establish the claim precisely, we need *canonical variables* for the Poisson bracket (1.2).

Motivated by the above question, in this paper we introduce canonical variables of the Poisson bracket (1.2), and study the Hamiltonian and Lagrangian formalisms of mutations in cluster algebras. As a consequence, the above observation is justified; furthermore, we can successfully explain how the dilogarithm identities in [Nak11b] naturally arise in the Hamiltonian/Lagrangian picture.

1.2. Outline and main results. Let us briefly describe the outline and the main results of the paper.

In Section 2, we recall basic definitions and properties of mutations in cluster algebras and of the dilogarithm functions which we are going to use.

In Section 3, we introduce the Hamiltonian formalism of mutations in cluster algebras with canonical variables. The x - and y -variables in a cluster algebra are constructed as exponentials of linear combinations of the canonical variables, while the Hamiltonian is given by the Euler dilogarithm. The time one flow of the Hamiltonian, together with the tropical transformation, yields the mutation of the x - and y -variables (Theorem 3.12). This naturally extends the Hamiltonian formalism in [FG09c]. An interesting feature here is that the y -variables mutate properly on the total phase space $M \simeq \mathbb{R}^{2n}$, while the x -variables do so only on a certain subspace M_0 of the phase space. This does not have an effect on the equations of motion; but does affect the *quantization* of the Poisson bracket in the following way:

- The canonical quantization of the Poisson bracket leads to the quantization of the y -variables by [FG09a, FG09c].
- On the other hand, the Poisson bracket on the small phase space M_0 is redefined via the *Dirac bracket* due to [Dir50]. Then, the “canonical quantization” of the Dirac bracket leads to the quantization of the x -variables by [BZ05].

Therefore, the formulation here provides a common platform for the quantization of both x - and y -variables.

In Section 4, having the canonical variables at hand, we study the Lagrangian formalism of mutations. A specific feature here is that the Hamiltonian in Section 3 is *singular*. This implies that we do not have a Lagrangian whose Euler-Lagrange equations are fully equivalent to the equations of motion of the Hamiltonian. Despite this deficiency, one can still define the Lagrangian through the Legendre transformation. Then, the following fact holds:

Fact 1. (Proposition 4.4) The Lagrangian coincides with the Rogers dilogarithm on the above small phase space M_0 .

This justifies the observation stated in the previous subsection.

In Section 5, we make a little detour to establish the periodicity property of the canonical variables. In the Hamiltonian formalism we naturally introduce a sign $\varepsilon = \pm$ to decompose each seed mutation into the tropical and nontropical parts. The mutation of x - and y -variables are independent of the choice of the sign ε , while the mutation of the canonical variables depends on it. Thus, we call these mutations *signed mutations*. We have the following result, which is crucial for obtaining the final result in the next section.

Fact 2. (Theorem 5.10) A sequence of signed mutations enjoys the same periodicity as a sequence of seed mutations, if we choose the sign sequence therein as the *tropical sign sequence*.

In Section 6, we show how the dilogarithm identities in [Nak11b] arise from the Hamiltonian/Lagrangian point of view. This is done by considering the *action integral* of the singular Lagrangian from Section 4 along a Hamiltonian flow. There are two key facts:

Fact 3. (Proposition 6.2) The Lagrangian is piecewise constant along the flow.

Fact 4. (Theorem 6.3) The action integral does not depend on the flow, if all flows are periodic for the time span of the integral. (This is regarded as the converse of a finite time analogue of Noether's theorem, see Remark 6.6.)

The dilogarithm identities in [Nak11b] are obtained as an immediate consequence of the above Facts 1–4. This is the main result of the paper (Theorem 6.8).

Remark 1.1. Every result in this paper can be straightforwardly extended to generalized cluster algebras and dilogarithm functions of higher degree studied in [Nak16].

Acknowledgements. The idea of regarding the relation between the Euler and Rogers dilogarithms appearing in the semiclassical analysis in [KN11] as a Legendre transformation was first suggested to T. N. by Junji Suzuki at the workshop “Infinite Analysis 11 Winter School: Quantum Cluster Algebras” held at Osaka University in December, 2011. We greatly thank him for his valuable suggestion. This work is supported in part by JSPS Grant No. 16H03922 to T. N. and by M.G.’s NSF grant No. 1362801.

2. PRELIMINARIES

2.1. Mutations in cluster algebras. Let us recall two main notions in cluster algebras, namely, a *seed* and its *mutation*. See [FZ02, FZ07] for more information on cluster algebras.

Let us fix a positive integer n throughout the paper. We say that an $n \times n$ integer matrix $B = (b_{ij})_{i,j=1}^n$ is *skew-symmetrizable* if there is a diagonal matrix

$D = \text{diag}(d_1, \dots, d_n)$ with positive integer diagonal entries d_1, \dots, d_n such that DB is skew-symmetric, i.e., $d_i b_{ij} = -d_j b_{ji}$. We call such D a *skew-symmetrizer* of B .

Let us fix a semifield \mathbb{P} , that is, an abelian multiplicative group with a binary operation \oplus called the *addition*, which is commutative, associative, and distributive, i.e., $a(b \oplus c) = ab \oplus ac$. Let $\mathbb{Z}\mathbb{P}$ be the group ring of \mathbb{P} . Since $\mathbb{Z}\mathbb{P}$ is a domain [FZ02], the field of fractions of $\mathbb{Z}\mathbb{P}$ is well defined and we denoted it by $\mathbb{Q}\mathbb{P}$. Let $\mathcal{F} = \mathcal{F}_{\mathbb{P}}$ be a purely transcendental field extension of $\mathbb{Q}\mathbb{P}$ of degree n , that is \mathcal{F} is isomorphic to a rational function field of n variables with coefficients in $\mathbb{Q}\mathbb{P}$. We call the semifield \mathbb{P} and the field \mathcal{F} the *coefficient semifield* and the *ambient field* (of a cluster algebra under consideration), respectively.

A *seed with coefficients in \mathbb{P}* is a triplet (B, x, y) consisting of an $n \times n$ skew-symmetrizable matrix B , an n -tuple $(x_i)_{i=1}^n$ of algebraically independent elements in \mathcal{F} , and an n -tuple $(y_i)_{i=1}^n$ of elements in \mathbb{P} . For each $k = 1, \dots, n$, the *mutation of a seed (B, x, y) at k* is another seed $(B', x', y') = \mu_k(B, x, y)$, which is obtained from (B, x, y) by the following formulas:

$$(2.1) \quad b'_{ij} = \begin{cases} -b_{ij} & i = k \text{ or } j = k \\ b_{ij} + [-\varepsilon b_{ik}]_+ b_{kj} + b_{ik} [\varepsilon b_{kj}]_+ & i, j \neq k, \end{cases}$$

$$(2.2) \quad x'_i = \begin{cases} x_k^{-1} \left(\prod_{j=1}^n x_j^{[-\varepsilon b_{jk}]_+} \right) \frac{1 + \hat{y}_k^\varepsilon}{1 \oplus y_k^\varepsilon} & i = k \\ x_i & i \neq k, \end{cases}$$

$$(2.3) \quad y'_i = \begin{cases} y_k^{-1} & i = k \\ y_i y_k^{[\varepsilon b_{ki}]_+} (1 \oplus y_k^\varepsilon)^{-b_{ki}} & i \neq k, \end{cases}$$

where

$$(2.4) \quad \hat{y}_i := y_i \prod_{j=1}^n x_j^{b_{ji}},$$

and ε is a sign, $+$ or $-$, which is naturally identified with 1 or -1 , respectively. Then we have the following properties:

- (1). The right hand sides of (2.1)–(2.3) are independent of the choice of sign ε .
- (2). If D is a skew-symmetrizer of B , then it is also a skew-symmetrizer of B' .
- (3). The mutation μ_k is involutive, namely,

$$(2.5) \quad \mu_k \circ \mu_k = \text{id}.$$

- (4). The \hat{y} -variables (2.4) also mutate in \mathcal{F} as the y -variables; namely,

$$(2.6) \quad \hat{y}'_i = \begin{cases} \hat{y}_k^{-1} & i = k \\ \hat{y}_i \hat{y}_k^{[\varepsilon b_{ki}]_+} (1 + \hat{y}_k^\varepsilon)^{-b_{ki}} & i \neq k. \end{cases}$$

Let us extract the “variable part” of the mutation μ_k in (2.2) and (2.3) as

$$(2.7) \quad \begin{aligned} \mu_k^B : \mathcal{F}^n \times \mathbb{P}^n &\rightarrow \mathcal{F}^n \times \mathbb{P}^n \\ (x, y) &\mapsto (x', y'), \end{aligned}$$

and call it the *mutation at k by B* . The involution property (2.5) is equivalent to the inversion relation,

$$(2.8) \quad \mu_k^{B_k} \circ \mu_k^B = \text{id},$$

where $B_k = B'$ is the one in (2.1).

Following the idea of [FG09a], we decompose the mutation μ_k^B into two parts. For each sign $\varepsilon = \pm$, we introduce a map

$$(2.9) \quad \begin{aligned} \rho_{k,\varepsilon}^B : \mathcal{F}^n \times \mathbb{P}^n &\rightarrow \mathcal{F}^n \times \mathbb{P}^n \\ (x, y) &\mapsto (\tilde{x}, \tilde{y}), \end{aligned}$$

$$(2.10) \quad \tilde{x}_i = x_i \left(\frac{1 + \hat{y}_k^\varepsilon}{1 \oplus y_k^\varepsilon} \right)^{-\delta_{ki}},$$

$$(2.11) \quad \tilde{y}_i = y_i (1 \oplus y_k^\varepsilon)^{-b_{ki}},$$

and also a map

$$(2.12) \quad \begin{aligned} \tau_{k,\varepsilon}^B : \mathcal{F}^n \times \mathbb{P}^n &\rightarrow \mathcal{F}^n \times \mathbb{P}^n \\ (x, y) &\mapsto (x', y'), \end{aligned}$$

$$(2.13) \quad x'_i = \begin{cases} x_k^{-1} \left(\prod_{j=1}^n x_j^{[-\varepsilon b_{jk}]_+} \right) & i = k \\ x_i & i \neq k, \end{cases}$$

$$(2.14) \quad y'_i = \begin{cases} y_k^{-1} & i = k \\ y_i y_k^{[\varepsilon b_{ki}]_+} & i \neq k. \end{cases}$$

Then, for each sign $\varepsilon = \pm$, the mutation μ_k^B is decomposed as

$$(2.15) \quad \mu_k^B = \tau_{k,\varepsilon}^B \circ \rho_{k,\varepsilon}^B.$$

In [FG09a], the transformations $\rho_{k,\varepsilon}^B$ and $\tau_{k,\varepsilon}^B$ for $\varepsilon = +$ were considered, and they were called the *automorphism part* and the *monomial part* of the mutation μ_k^B , respectively. Here, we call $\rho_{k,\varepsilon}^B$ and $\tau_{k,\varepsilon}^B$ the *nontropical part* and the *tropical part* of the mutation μ_k^B , respectively. See [Nak12] for the background of the terminology.

When the coefficient field \mathbb{P} is taken to be the *trivial semifield* $\mathbf{1} = \{1\}$, where $1 \oplus 1 = 1$, we say that the x -variables are *without coefficients*. In that case the transformations (2.2) and (2.10) are simplified as

$$(2.16) \quad x'_i = \begin{cases} x_k^{-1} \left(\prod_{j=1}^n x_j^{[-\varepsilon b_{jk}]_+} \right) (1 + \hat{y}_k^\varepsilon) & i = k \\ x_i & i \neq k, \end{cases}$$

$$(2.17) \quad \tilde{x}_i = x_i (1 + \hat{y}_k^\varepsilon)^{-\delta_{ki}},$$

respectively, while (2.4) also reduces to

$$(2.18) \quad \hat{y}_i = \prod_{j=1}^n x_j^{b_{ji}}.$$

2.2. Euler and Rogers dilogarithm functions. Let us recall the definition of the Euler and Rogers dilogarithms. See [Lew81, Zag07] for more information.

The *Euler dilogarithm* $\text{Li}_2(x)$ is originally defined as the following convergent series with radius of convergence 1,

$$(2.19) \quad \text{Li}_2(x) = \sum_{n=1}^{\infty} \frac{x^n}{n^2}.$$

It has the integral expression

$$(2.20) \quad \text{Li}_2(x) = - \int_0^x \frac{\log(1-y)}{y} dy, \quad (x \leq 1),$$

where throughout the text we concentrate on the real region $x \leq 1$ so that there is no ambiguity due to multivaluedness of the integral. Note that (2.20) is also written as

$$(2.21) \quad \text{Li}_2(-x) = - \int_0^x \frac{\log(1+y)}{y} dy, \quad (-1 \leq x).$$

On the other hand, the *Rogers dilogarithm* $L(x)$ is defined by the integral expression

$$(2.22) \quad L(x) = -\frac{1}{2} \int_0^x \left\{ \frac{\log(1-y)}{y} + \frac{\log y}{1-y} \right\} dy, \quad (0 \leq x \leq 1).$$

Again, since we concentrate on the real region $0 \leq x \leq 1$, there is no ambiguity due to multivaluedness of the integral.

These two dilogarithms are related by

$$(2.23) \quad L(x) = \text{Li}_2(x) + \frac{1}{2} \log x \log(1-x), \quad (0 \leq x \leq 1),$$

which can be used as an alternative definition of the Rogers dilogarithm. They are also related by the following less well-known formula:

$$(2.24) \quad L\left(\frac{x}{1+x}\right) = -\text{Li}_2(-x) - \frac{1}{2} \log x \log(1+x), \quad (0 \leq x)$$

$$(2.25) \quad = \frac{1}{2} \int_0^x \left\{ \frac{\log(1+y)}{y} - \frac{\log y}{1+y} \right\} dy, \quad (0 \leq x).$$

Formulas (2.23)–(2.25) can be most easily verified by taking the derivative.

In view of the formulas (2.24) and (2.25), it is convenient to introduce a function

$$(2.26) \quad \tilde{L}(x) = L\left(\frac{x}{1+x}\right) = \frac{1}{2} \int_0^x \left\{ \frac{\log(1+y)}{y} - \frac{\log y}{1+y} \right\} dy, \quad (0 \leq x),$$

so that it satisfies the equality

$$(2.27) \quad \tilde{L}(x) = -\text{Li}_2(-x) - \frac{1}{2} \log x \log(1+x), \quad (0 \leq x).$$

For simplicity, we still call the function $\tilde{L}(x)$ the Rogers dilogarithm.

3. HAMILTONIAN FORMALISM OF MUTATIONS

3.1. Canonical and log-canonical variables. Let M be a symplectic manifold with a global Darboux chart $\varphi : M \xrightarrow{\sim} \mathbb{R}^{2n}$. Let (u, p) , $u = (u_1, \dots, u_n)$, $p = (p_1, \dots, p_n)$, be the *canonical coordinates* of the chart. Then, in the coordinates (u, p) , the *Poisson bracket* is given by

$$(3.1) \quad \{f, g\} = \sum_{i=1}^n \left(\frac{\partial f}{\partial p_i} \frac{\partial g}{\partial u_i} - \frac{\partial g}{\partial p_i} \frac{\partial f}{\partial u_i} \right)$$

for any (smooth) functions f and g on M . We call M the *phase space*.

We recall some basic properties of the Poisson bracket which we use below.

(1) We have

$$(3.2) \quad \{p_i, u_j\} = \delta_{ij}, \quad \{u_i, u_j\} = \{p_i, p_j\} = 0.$$

(2) For any function f on M ,

$$(3.3) \quad \{f, p_i\} = -\frac{\partial f}{\partial u_i}, \quad \{f, u_i\} = \frac{\partial f}{\partial p_i}.$$

(3) For any functions f and g on M , and any smooth functions $F(\zeta)$ and $G(\zeta)$ of a single variable ζ ,

$$(3.4) \quad \{F(f), G(g)\} = \{f, g\}F'(f)G'(g).$$

In particular, the following formula holds:

$$(3.5) \quad \{e^f, e^g\} = \{f, g\}e^f e^g.$$

Let us fix any $n \times n$ skew-symmetrizable (integer) matrix $B = (b_{ij})_{i,j=1}^n$ with a skew-symmetrizer D . We introduce variables (i.e., functions on M) w_i, x_i, y_i ($i = 1, \dots, n$) as follows:

$$(3.6) \quad w_i = \sum_{j=1}^n b_{ji} u_j,$$

$$(3.7) \quad x_i = e^{2u_i},$$

$$(3.8) \quad y_i = e^{d_i p_i + w_i}.$$

Lemma 3.1. *We have the following formulas:*

$$(3.9) \quad \{d_i p_i + w_i, d_j p_j + w_j\} = 2d_i b_{ij}, \quad \{d_i p_i + w_i, u_j\} = d_i \delta_{ij}.$$

Definition 3.2. Following [GSV03], we say that a family of variables z_1, \dots, z_m are *log-canonical* if their pairwise Poisson brackets are of the form

$$(3.10) \quad \{z_i, z_j\} = c_{ij} z_i z_j,$$

where each c_{ij} is a constant.

Proposition 3.3. *The variables x_1, \dots, x_n and y_1, \dots, y_n are log-canonical with the following Poisson brackets:*

$$(3.11) \quad \{x_i, x_j\} = 0, \quad \{y_i, y_j\} = 2d_i b_{ij} y_i y_j, \quad \{y_i, x_j\} = 2d_i \delta_{ij} y_i x_j.$$

Proof. Follows from (3.2), (3.5), and Lemma 3.1. \square

3.2. Hamiltonian for infinitesimal nontropical mutation. For any $k \in \{1, \dots, n\}$ and a sign $\varepsilon = \pm$, we introduce the *Hamiltonian function* $H_{k,\varepsilon}^B$ on M by

$$(3.12) \quad H_{k,\varepsilon}^B = \frac{\varepsilon}{2d_k} \text{Li}_2(-y_k^\varepsilon) = -\frac{\varepsilon}{2d_k} \int_0^{y_k^\varepsilon} \frac{\log(1+z)}{z} dz,$$

where $\text{Li}_2(x)$ is the Euler dilogarithm (2.20), and we used the expression (2.21).

Let t be the time variable. We consider the Hamiltonian flow on the phase space M by the Hamiltonian $H_{k,\varepsilon}^B$. Accordingly, we have functions of t , $u_i(t)$, $p_i(t)$, $w_i(t)$, etc., which obey the following *equations of motion*, where we use the standard notation $\dot{f} = df/dt$.

Proposition 3.4. (1) *The equations of motion are given as follows:*

$$(3.13) \quad \dot{u}_i(t) = \{H_{k,\varepsilon}^B, u_i(t)\} = -\frac{1}{2}\delta_{ki} \log(1 + y_k(t)^\varepsilon),$$

$$(3.14) \quad \dot{p}_i(t) = \{H_{k,\varepsilon}^B, p_i(t)\} = -\frac{1}{2d_i}b_{ki} \log(1 + y_k(t)^\varepsilon),$$

$$(3.15) \quad \dot{w}_i(t) = \{H_{k,\varepsilon}^B, w_i(t)\} = -\frac{1}{2}b_{ki} \log(1 + y_k(t)^\varepsilon),$$

$$(3.16) \quad d_i\dot{p}_i(t) = \{H_{k,\varepsilon}^B, d_i p_i(t)\} = -\frac{1}{2}b_{ki} \log(1 + y_k(t)^\varepsilon),$$

$$(3.17) \quad \dot{x}_i(t) = \{H_{k,\varepsilon}^B, x_i(t)\} = -\delta_{ki} \log(1 + y_k(t)^\varepsilon) \cdot x_i(t),$$

$$(3.18) \quad \dot{y}_i(t) = \{H_{k,\varepsilon}^B, y_i(t)\} = -b_{ki} \log(1 + y_k(t)^\varepsilon) \cdot y_i(t).$$

(2) *In particular, $\dot{y}_k(t) = 0$, so that $y_k(t)$ in the right hand sides of (3.13)–(3.18) does not depend on t .*

Proof. For example,

$$(3.19) \quad \begin{aligned} \{H_{k,\varepsilon}^B, u_i\} &= \frac{\partial H_{k,\varepsilon}^B}{\partial p_i} = \frac{dH_{k,\varepsilon}^B}{dy_k^\varepsilon} \frac{dy_k^\varepsilon}{dy_k} \frac{\partial y_k}{\partial p_i} \\ &= \left(-\frac{\varepsilon}{2d_k} \frac{\log(1 + y_k^\varepsilon)}{y_k^\varepsilon}\right) (\varepsilon y_k^{\varepsilon-1}) (\delta_{ki} d_k y_k) = -\frac{1}{2}\delta_{ki} \log(1 + y_k^\varepsilon), \end{aligned}$$

$$(3.20) \quad \begin{aligned} \{H_{k,\varepsilon}^B, p_i\} &= -\frac{\partial H_{k,\varepsilon}^B}{\partial u_i} = -\frac{dH_{k,\varepsilon}^B}{dy_k^\varepsilon} \frac{dy_k^\varepsilon}{dy_k} \frac{\partial y_k}{\partial u_i} \\ &= -\left(-\frac{\varepsilon}{2d_k} \frac{\log(1 + y_k^\varepsilon)}{y_k^\varepsilon}\right) (\varepsilon y_k^{\varepsilon-1}) (b_{ik} y_k) = -\frac{1}{2d_i}b_{ki} \log(1 + y_k^\varepsilon), \end{aligned}$$

where $d_i b_{ik} = -d_k b_{ki}$ is used for the last equality. \square

From Proposition 3.4 one can also observe the following. (In fact, it is a direct consequence of the fact that $H_{k,\varepsilon}^B$ only depends on the variable $y_k = \exp(d_k p_k + w_k)$.)

Proposition 3.5. (1) *The variables $u_1, \dots, u_{k-1}, u_{k+1}, \dots, u_n$ and p_k are integrals of motion in involution. Therefore, the Hamiltonian $H_{k,\varepsilon}^B$ is completely integrable.*

(2) *The flows of the variables u_k and $p_1, \dots, p_{k-1}, p_{k+1}, \dots, p_n$ are linear in t .*

Let us consider a *time one flow*

$$(3.21) \quad \begin{aligned} \rho_{k,\varepsilon}^B : \quad \mathbb{R}^{2n} &\rightarrow \mathbb{R}^{2n} \\ (u, p) &\mapsto (\tilde{u}, \tilde{p}), \end{aligned}$$

which is defined by the Hamiltonian flow from time $t = 0$ to $t = 1$. Let $\tilde{w}_i, \tilde{x}_i, \tilde{y}_i$ be the corresponding flows of w_i, x_i, y_i , respectively. Let \mathbb{R}_+ be the semifield of all positive real numbers, where the multiplication and the addition are given by the ordinary ones for real numbers.

Proposition 3.6. *We have the following formulas:*

$$(3.22) \quad \tilde{u}_i = u_i - \frac{1}{2} \delta_{ki} \log(1 + y_k^\varepsilon),$$

$$(3.23) \quad \tilde{p}_i = p_i - \frac{1}{2d_i} b_{ki} \log(1 + y_k^\varepsilon),$$

$$(3.24) \quad \tilde{w}_i = w_i - \frac{1}{2} b_{ki} \log(1 + y_k^\varepsilon),$$

$$(3.25) \quad d_i \tilde{p}_i = d_i p_i - \frac{1}{2} b_{ki} \log(1 + y_k^\varepsilon),$$

$$(3.26) \quad \tilde{x}_i = x_i (1 + y_k^\varepsilon)^{-\delta_{ki}},$$

$$(3.27) \quad \tilde{y}_i = y_i (1 + y_k^\varepsilon)^{-b_{ki}}.$$

In particular, the transformation (3.27) coincides with the nontropical part of the mutation of the y -variables in (2.11) with $\mathbb{P} = \mathbb{R}_+$.

Proof. This follows from Proposition 3.4. \square

Therefore, the Hamiltonian $H_{k,\varepsilon}^B$ provides the infinitesimal generator of the nontropical mutation of y -variables of seeds. This Hamiltonian viewpoint of mutations (without employing the canonical variables u_i and p_i) was first stated in [FG09c, Section 1.3] for $\varepsilon = 1$.

3.3. Small phase space and x -variables. The transformation (3.26) of x -variables is comparable to the nontropical part of the mutation of x -variables *without coefficients* from (2.17). However, in contrast to the y -variable case, they do *not* exactly match due to the discrepancy between y_k and \hat{y}_k therein. To remedy this situation, we introduce a subspace of the phase space M ,

$$(3.28) \quad M_0 = \{\varphi^{-1}(u, p) \in M \mid d_i p_i - w_i = 0, (i = 1, \dots, n)\},$$

and we call it the *small phase space*.

Proposition 3.7. *The small phase space M_0 is preserved under the Hamiltonian flow by $H_{k,\varepsilon}^B$.*

Proof. This follows from (3.15) and (3.16). \square

Let us introduce new variables \hat{y}_i ($i = 1, \dots, n$) by

$$(3.29) \quad \hat{y}_i := e^{2w_i} = e^{2 \sum_{j=1}^n b_{ji} u_j} = \prod_{j=1}^n x_j^{b_{ji}}.$$

Since $d_i p_i = w_i$ on M_0 , we have

$$(3.30) \quad y_i = \hat{y}_i \quad \text{on } M_0.$$

Thus, the transformation (3.26) assumes the desired form on M_0 :

Proposition 3.8.

$$(3.31) \quad \tilde{x}_i = x_i (1 + \hat{y}_k^\varepsilon)^{-\delta_{ki}} \quad \text{on } M_0,$$

In particular, the transformation (3.31) restricted to M_0 coincides with the nontropical part of the mutation of the x -variables without coefficients in (2.17).

3.4. Tropical transformation. To complete the picture, we also give a realization of the tropical transformations (2.13) and (2.14) through a *change of coordinates* of the phase space M . For any $k \in \{1, \dots, n\}$ and a sign $\varepsilon = \pm$, we consider the following transformation:

$$(3.32) \quad \begin{aligned} \tau_{k,\varepsilon}^B : \mathbb{R}^{2n} &\rightarrow \mathbb{R}^{2n} \\ (u, p) &\mapsto (u', p') \end{aligned}$$

$$(3.33) \quad u'_i = \begin{cases} -u_k + \sum_{j=1}^n [-\varepsilon b_{jk}]_+ u_j & i = k \\ u_i & i \neq k, \end{cases}$$

$$(3.34) \quad p'_i = \begin{cases} -p_k & i = k \\ p_i + [-\varepsilon b_{ik}]_+ p_k & i \neq k. \end{cases}$$

We call the transformation $\tau_{k,\varepsilon}^B$ a *tropical transformation*. Note that it is an ordinary linear transformation, not a *piecewise linear* transformation.

Proposition 3.9. *Let $\tau_{k,\varepsilon}^B(u, p) = (u', p')$.*

(1) *We have*

$$(3.35) \quad \sum_{i=1}^n u'_i p'_i = \sum_{i=1}^n u_i p_i.$$

(2) *The transformation $\tau_{k,\varepsilon}^B$ is canonical; namely, we have*

$$(3.36) \quad \{p'_i, u'_j\} = \delta_{ij}, \quad \{u'_i, u'_j\} = \{p'_i, p'_j\} = 0.$$

Proof. We write the linear transformations (3.33) and (3.34) in the matrix form as $u' = Mu$ and $p' = Np$. Then, $N^T M = I$ holds. Both properties (1) and (2) follow from it. \square

By Proposition 3.9 (2), one can introduce a new global Darboux chart $\varphi' : M \xrightarrow{\sim} \mathbb{R}^{2n}$ with canonical coordinates (u', p') by the following commutative diagram:

$$(3.37) \quad \begin{array}{ccc} & M & \\ \varphi \swarrow & & \searrow \varphi' \\ \mathbb{R}^{2n} & \xrightarrow{\tau_{k,\varepsilon}^B} & \mathbb{R}^{2n} \end{array}$$

Let $B' = B_k$. We employ a common skew-symmetrizer D for B and B' , and we define primed variables w'_i, x'_i, y'_i for $(u', p') = \tau_{k,\varepsilon}^B(u, p)$,

$$(3.38) \quad w'_i = \prod_{j=1}^n b'_{ji} u'_j,$$

$$(3.39) \quad x'_i = e^{2u'_i},$$

$$(3.40) \quad y'_i = e^{d_i p'_i + w'_i}.$$

Proposition 3.10. *We have the following formulas:*

$$(3.41) \quad w'_i = \begin{cases} -w_k & i = k \\ w_i + [\varepsilon b_{ki}]_+ w_k & i \neq k, \end{cases}$$

$$(3.42) \quad d_i p'_i = \begin{cases} -d_k p_k & i = k \\ d_i p_i + [\varepsilon b_{ki}]_+ d_k p_k & i \neq k, \end{cases}$$

$$(3.43) \quad x'_i = \begin{cases} x_k^{-1} \left(\prod_{j=1}^n x_j^{[-\varepsilon b_{jk}]_+} \right) & i = k \\ x_i & i \neq k, \end{cases}$$

$$(3.44) \quad y'_i = \begin{cases} y_k^{-1} & i = k \\ y_i y_k^{[\varepsilon b_{ki}]_+} & i \neq k. \end{cases}$$

In particular, the transformations (3.43) and (3.44) coincide with the tropical part of the mutation of the x - and y -variables in (2.13) and (2.14), respectively.

Proof. To prove (3.41), we use (2.1) together with (3.33) and (3.34). \square

Proposition 3.11. *In the new global Darboux chart $\varphi' : M \xrightarrow{\sim} \mathbb{R}^{2n}$, the small phase space M_0 is given by*

$$(3.45) \quad M_0 = \{\varphi'^{-1}(u', p') \in M \mid d_i p'_i - w'_i = 0, (i = 1, \dots, n)\}.$$

Proof. This follows from (3.41) and (3.42). \square

3.5. Signed mutations. Let us introduce a composition of maps

$$(3.46) \quad \mu_{k,\varepsilon}^B = \tau_{k,\varepsilon}^B \circ \rho_{k,\varepsilon}^B : \quad \begin{array}{ccc} \mathbb{R}^{2n} & \rightarrow & \mathbb{R}^{2n} \\ (u, p) & \mapsto & (u', p'). \end{array}$$

Summarizing Propositions 3.6, 3.8, and 3.10, we have the following conclusion.

Theorem 3.12. *Let $\mu_{k,\varepsilon}^B(u, p) = (u', p')$. Then, we have the following formulas:*

$$(3.47) \quad u'_i = \begin{cases} -u_k + \sum_{j=1}^n [-\varepsilon b_{jk}]_+ u_j + \frac{1}{2} \log(1 + y_k^\varepsilon) & i = k \\ u_i & i \neq k, \end{cases}$$

$$(3.48) \quad p'_i = \begin{cases} -p_k & i = k \\ p_i + [-\varepsilon b_{ik}]_+ p_k - \frac{1}{2d_i} b_{ki} \log(1 + y_k^\varepsilon) & i \neq k, \end{cases}$$

$$(3.49) \quad w'_i = \begin{cases} -w_k & i = k \\ w_i + [\varepsilon b_{ki}]_+ w_k - \frac{1}{2} b_{ki} \log(1 + y_k^\varepsilon), & i \neq k, \end{cases}$$

$$(3.50) \quad d_i p'_i = \begin{cases} -d_k p_k & i = k \\ d_i p_i + [\varepsilon b_{ki}]_+ d_k p_k - \frac{1}{2} b_{ki} \log(1 + y_k^\varepsilon) & i \neq k, \end{cases}$$

$$(3.51) \quad x'_i = \begin{cases} x_k^{-1} \left(\prod_{j=1}^n x_j^{[-\varepsilon b_{jk}]_+} \right) (1 + y_k^\varepsilon) & i = k \\ x_i & i \neq k, \end{cases}$$

$$(3.52) \quad y'_i = \begin{cases} y_k^{-1} & i = k \\ y_i y_k^{[\varepsilon b_{ki}]_+} (1 + y_k^\varepsilon)^{-b_{ki}} & i \neq k. \end{cases}$$

In particular, the transformation (3.52) coincides with the mutation of the y -variables in (2.3) with $\mathbb{P} = \mathbb{R}_+$, while the transformation (3.51) restricted to M_0 coincides with the mutation of the x -variables without coefficients in (2.16).

As a corollary of Theorem 3.12, x' on M_0 and y' therein do not depend on the choice of the sign ε . However, u' and p' do depend on ε . Thus, we call the map $\mu_{k,\varepsilon}^B$ in (3.46) the *signed mutation at k by B with sign ε* .

The inversion relation (2.8) of the unsigned mutation μ_k^B is replaced with the following one:

Proposition 3.13. *Define $\rho_{k,\varepsilon}^B$ and $\rho_{k,-\varepsilon}^{B_k}$ by a common skew-symmetrizer D of B and B_k . Then, the following inversion relation holds:*

$$(3.53) \quad \mu_{k,-\varepsilon}^{B_k} \circ \mu_{k,\varepsilon}^B = \text{id}.$$

Proof. One can directly verify it by (3.47) and (3.48). \square

3.6. Canonical quantization. One can canonically quantize the Poisson brackets in (3.2) by replacing them with the canonical commutation relations,

$$(3.54) \quad [P_i, U_j] = \frac{\hbar}{\sqrt{-1}} \delta_{ij}, \quad [U_i, U_j] = [P_i, P_j] = 0.$$

Then, we have

$$(3.55) \quad [d_i P_i + W_i, d_j P_j + W_j] = \frac{2\hbar}{\sqrt{-1}} d_i b_{ij} = 2\hbar \sqrt{-1} d_j b_{ji}.$$

Let us set

$$(3.56) \quad q = e^{\hbar \sqrt{-1}}.$$

We recall a special case of the Baker-Campbell-Hausdorff formula. For any non-commutative variables A and B such that $[A, B] = C$ and $[C, A] = [C, B] = 0$, we have

$$(3.57) \quad e^A e^B = e^{C/2} e^{A+B},$$

or

$$(3.58) \quad e^A e^B = e^C e^B e^A.$$

Applying it for (3.55), we have the commutation relation for $Y_i = e^{d_i P_i + W_i}$,

$$(3.59) \quad Y_i Y_j = q^{2d_j b_{ji}} Y_j Y_i.$$

This coincides with the quantization of y -variables due to Fock and Goncharov [FG09a, FG09c].

Remark 3.14. The realization of quantum y -variables by the canonical variables presented here appeared in [FG09b, KN11, Nak16]. In fact, the construction of x - and y -variables in (3.7) and (3.8) is deduced from the quantum ones in [KN11, Nak16].

3.7. Quantization of x -variables through Dirac bracket. Since x -variables are in involution for the Poisson bracket (3.11), the canonical quantization in (3.54) only provides the trivial quantization for them. However, by Proposition 3.8, they should be restricted to the small phase space M_0 to be identified with the x -variables in a seed. Therefore, we should apply Dirac's method [Dir50] to obtain the Poisson structure on M_0 .

Recall that the space M_0 is given by a family of constraints $\chi_i = 0$ ($i = 1, \dots, n$), where

$$(3.60) \quad \chi_i = d_i p_i - w_i.$$

Following [Dir50], let us consider the $n \times n$ matrix $A = (a_{ij})_{i,j=1}^n$ defined by

$$(3.61) \quad a_{ij} := \{\chi_i, \chi_j\} = -2d_i b_{ij}.$$

To proceed, we have to assume that the matrix $A = -2DB$ is invertible, or equivalently, B is invertible. Then, we have $A^{-1} = -(1/2)B^{-1}D^{-1}$.

Lemma 3.15. *The matrix B^{-1} is skew-symmetrizable with D being its skew-symmetrizer.*

Proof. By assumption, we have $DBD^{-1} = -B^T$. Taking its inverse, we have $DB^{-1}D^{-1} = -(B^{-1})^T$. \square

The *Dirac bracket* is defined by

$$(3.62) \quad \{f, g\}_D := \{f, g\} - \sum_{i,j=1}^n \{f, \chi_i\} (A^{-1})_{ij} \{\chi_j, g\},$$

where $(A^{-1})_{ij}$ is the (i, j) -component of A^{-1} .

Here are some basic properties of the Dirac bracket.

- (1) It defines a new Poisson bracket on M .
- (2) For any constraint function χ_i and any function f on M ,

$$(3.63) \quad \{f, \chi_i\}_D = 0$$

holds. Thus, for any function g on M , $\{f, g\chi_i\}_D = \{f, g\}_D \chi_i$ vanishes on M_0 . As a consequence, it defines a Poisson bracket on M_0 .

(3) For any function f on M ,

$$(3.64) \quad \{H_{k,\varepsilon}^B, f\}_D = \{H_{k,\varepsilon}^B, f\},$$

since $\{H_{k,\varepsilon}^B, \chi_i\} = 0$ as stated in Proposition 3.7. Therefore, the equations of motion do not change.

It is convenient to set $B^{-1} = \Omega = (\omega_{ij})_{i,j=1}^n$.

Proposition 3.16. *We have the following formulas:*

$$(3.65) \quad \{p_i, u_j\}_D = \frac{1}{2}\delta_{ij}, \quad \{u_i, u_j\}_D = -\frac{1}{2}d_i\omega_{ij}, \quad \{p_i, p_j\}_D = \frac{1}{2d_j}b_{ij},$$

$$(3.66) \quad \{x_i, x_j\}_D = -2d_i\omega_{ij}x_ix_j, \quad \{\hat{y}_i, \hat{y}_j\}_D = 2d_ib_{ij}\hat{y}_i\hat{y}_j, \quad \{\hat{y}_i, x_j\}_D = 2d_i\delta_{ij}\hat{y}_ix_j,$$

where \hat{y}_i is defined by (3.29).

Proof. The formulas in (3.65) are obtained by explicit calculations from the definition (3.62). Note that $\hat{y}_i = e^{2d_ip_i}$ on M_0 . Then, we apply (3.5) to obtain (3.66). \square

In particular, the Dirac brackets in (3.66) for x - and \hat{y} -variables coincide with the Poisson brackets in [GSV03].

Now we “canonically quantize” the Dirac brackets in (3.65) by replacing them with the commutation relations,

$$(3.67) \quad [P_i, U_j] = \frac{\hbar}{\sqrt{-1}}\frac{1}{2}\delta_{ij}, \quad [U_i, U_j] = \frac{\hbar}{\sqrt{-1}}\frac{-1}{2}d_i\omega_{ij}, \quad [P_i, P_j] = \frac{\hbar}{\sqrt{-1}}\frac{1}{2d_j}b_{ij}.$$

Then, in the same manner as in the previous subsection, we obtain the following commutation relation for $X_i = e^{2U_i}$,

$$(3.68) \quad X_i X_j = q^{2d_i\omega_{ij}} X_j X_i.$$

This coincides with the quantization of x -variables (without coefficients) due to Berenstein and Zelevinsky [BZ05], where the skew-symmetric matrix Λ therein is related to Ω via $\Lambda^T = D\Omega$, and q therein is identified with q^{-2} here.

4. LAGRANGIAN FORMALISM AND ROGERS DILOGARITHM

4.1. Legendre transformation. Let us recall some basic facts on the Legendre transformation of a Hamiltonian. See, for example, [AM78, Tak08] for more information.

For simplicity, let us consider a Hamiltonian H on the space \mathbb{R}^{2n} with the canonical coordinates (u, p) . The space \mathbb{R}^{2n} is naturally identified with the cotangent bundle $\pi : T^*\mathbb{R}^n \rightarrow \mathbb{R}^n$, where $\pi(u, p) = u$ and $p = (p_i)_{i=1}^n$ represents the 1-form $\sum_{i=1}^n p_i du_i$. Then, the Hamiltonian H induces the following fiber preserving map:

$$(4.1) \quad \begin{aligned} F_H : T^*\mathbb{R}^n &\rightarrow T\mathbb{R}^n \\ (u, p) &\mapsto (u, \dot{u}). \end{aligned}$$

Definition 4.1. We say that a Hamiltonian $H(u, p)$ is *regular* if the map F_H is a diffeomorphism.

The *Lagrangian* \mathcal{L} for the Hamiltonian H is formally defined by the *Legendre transformation*,

$$(4.2) \quad \mathcal{L} = \sum_{i=1}^n \dot{u}_i p_i - H.$$

Here we use the symbol \mathcal{L} so that it is not confused with the Rogers dilogarithm $L(x)$ or $\tilde{L}(x)$. From the definition \mathcal{L} is a function of $(u, p) \in T^*\mathbb{R}^n$. Assume that the Hamiltonian H is regular. Then, by the inverse map of F_H , one can convert it to a function of (u, \dot{u}) , which is the Lagrangian function $\mathcal{L}(u, \dot{u})$. The equations of motion of the Hamiltonian H are equivalent to the *Euler-Lagrange equations*

$$(4.3) \quad \frac{d}{dt} \left(\frac{\partial \mathcal{L}}{\partial \dot{u}_i} \right) = \frac{\partial \mathcal{L}}{\partial u_i},$$

together with the identification of variables p_i ,

$$(4.4) \quad p_i = \frac{\partial \mathcal{L}}{\partial \dot{u}_i}.$$

There is a parallel notion of regularity for a Lagrangian.

Definition 4.2. We say that a Lagrangian $\mathcal{L}(u, \dot{u})$ is *regular* if the map

$$(4.5) \quad \begin{array}{ccc} F_{\mathcal{L}} : & T\mathbb{R}^n & \rightarrow T^*\mathbb{R}^n \\ & (u, \dot{u}) & \mapsto (u, p). \end{array}$$

is a diffeomorphism, where p_i is defined by (4.4).

It is known (e.g., [AM78, Sec. 3.6]) that from a regular Hamiltonian one obtains a regular Lagrangian by the Legendre transformation; conversely, from a regular Lagrangian one obtains a regular Hamiltonian by the Legendre transformation. In either case the two systems are equivalent in the above sense.

4.2. Lagrangian and Rogers dilogarithm. Let us consider the Hamiltonian $H = H_{k,\varepsilon}^B$ from (3.12) in the canonical coordinates (u, p) . By (3.13), we have

$$(4.6) \quad \dot{u}_i = -\frac{1}{2} \delta_{ki} \log(1 + y_k^\varepsilon).$$

Thus, the map F_H in (4.1) is far from surjective. Therefore, the Hamiltonian H is singular (i.e., not regular), unfortunately.

Nevertheless, let us write the Lagrangian in (4.2) explicitly, for now, as a function of (u, p) ,

$$(4.7) \quad \mathcal{L}_{k,\varepsilon}^B(u, p) = -\frac{1}{2} \log(1 + y_k^\varepsilon) p_k - \frac{\varepsilon}{2d_k} \text{Li}_2(-y_k^\varepsilon).$$

Inverting the relation (4.6) for $i = k$, we regard y_k as a function of \dot{u}_k . Then, we also regard p_k as a function of \dot{u}_k and $u_1, \dots, u_{k-1}, u_{k+1}, \dots, u_n$ by the relation

$$(4.8) \quad p_k = d_k^{-1} (\log y_k - w_k).$$

Thus, the function $\mathcal{L}_{k,\varepsilon}^B(u, p)$ is converted to a function of (u, \dot{u}) by

$$(4.9) \quad \mathcal{L}_{k,\varepsilon}^B(u, \dot{u}) = -\frac{1}{2d_k} \log(1 + y_k^\varepsilon) (\log y_k - w_k) - \frac{\varepsilon}{2d_k} \text{Li}_2(-y_k^\varepsilon),$$

despite the fact that the Hamiltonian is singular.

Of course, we have to pay some price. The Lagrangian $\mathcal{L}_{k,\varepsilon}^B(u, \dot{u})$ is *singular*, since it is independent of the variables \dot{u}_i for $i \neq k$. Moreover, it is *not* equivalent to the original Hamiltonian system.

Proposition 4.3. (1) For $i = k$, the equation (4.3), together with (4.4), yields

$$(4.10) \quad y_k(t) = e^{d_k p_k(t) + w_k(t)}, \quad \dot{p}_k(t) = 0.$$

(2) For $i \neq k$, the equation (4.3), together with (4.4), yields

$$(4.11) \quad p_i(t) = 0, \quad b_{ki} \log(1 + y_k(t)^\varepsilon) = 0.$$

Proof. (1) For $i = k$,

$$(4.12) \quad \frac{\partial \mathcal{L}}{\partial \dot{u}_k} = \frac{1}{d_k} (\log y_k - w_k),$$

$$(4.13) \quad \frac{\partial \mathcal{L}}{\partial u_k} = 0.$$

(2) For $i \neq k$,

$$(4.14) \quad \frac{\partial \mathcal{L}}{\partial \dot{u}_i} = 0,$$

$$(4.15) \quad \frac{\partial \mathcal{L}}{\partial u_i} = \frac{b_{ik}}{2d_k} \log(1 + y_k^\varepsilon) = -\frac{b_{ki}}{2d_i} \log(1 + y_k^\varepsilon).$$

□

Therefore, the Euler-Lagrange equation for $i = k$ is a part of the equations of motion of the original Hamiltonian system in Proposition 3.4. On the other hand, the ones for $i \neq k$ set an unwanted restriction (4.11), and we have to avoid using them.

Putting this defect aside, let us evaluate $\mathcal{L}_{k,\varepsilon}^B$ on the small phase space M_0 . Recall that we have $y_k = e^{2d_k p_k}$ on M_0 . Thus, we have

$$(4.16) \quad p_k = \frac{1}{2d_k} \log y_k = \frac{\varepsilon}{2d_k} \log y_k^\varepsilon \quad \text{on } M_0.$$

Thus, $\mathcal{L}_{k,\varepsilon}^B$ depends only on y_k , or equivalently, on y_k^ε . So, let us write it as a function of y_k^ε as $\mathcal{L}_{k,\varepsilon}^B(y_k^\varepsilon)$ for our convenience. Then, putting it in (4.7), we obtain

$$(4.17) \quad \mathcal{L}_{k,\varepsilon}^B(y_k^\varepsilon) = -\frac{\varepsilon}{4d_k} \log y_k^\varepsilon \log(1 + y_k^\varepsilon) - \frac{\varepsilon}{2d_k} \text{Li}_2(-y_k^\varepsilon).$$

Now the Rogers dilogarithm emerges in our picture.

Proposition 4.4. The function $\mathcal{L}_{k,\varepsilon}^B(y_k^\varepsilon)$ is given by the Rogers dilogarithm $\tilde{L}(x)$ in (2.26) as

$$(4.18) \quad \mathcal{L}_{k,\varepsilon}^B(y_k^\varepsilon) = \frac{\varepsilon}{2d_k} \tilde{L}(y_k^\varepsilon).$$

Proof. This follows from (2.27) and (4.17). □

Let us boldly phrase the above result as “the Rogers dilogarithm is a Legendre transformation of the Euler dilogarithm.” This justifies the observation stated in Section 1.1.

5. PERIODICITY OF CANONICAL VARIABLES

5.1. Universal and tropical semifields. Let us recall two important classes of semifields, following [FZ07].

Definition 5.1. Let $z = (z_1, \dots, z_n)$ be an n -tuple of formal commutative variables.

(1) Define a semifield

$$(5.1) \quad \mathbb{Q}_+(z) = \left\{ \frac{p(z)}{q(z)} \in \mathbb{Q}(z) \mid p(z) \text{ and } q(z) \text{ are nonzero polynomials of } z \right. \\ \left. \text{with nonnegative integer coefficients} \right\},$$

where the multiplication and the addition \oplus are given by the ordinary ones for the rational function field $\mathbb{Q}(z)$. We call it the *universal semifield of z* .

(2) Define a semifield

$$(5.2) \quad \text{Trop}(z) = \left\{ \prod_{i=1}^n z_i^{a_i} \mid a_i \in \mathbb{Z} \right\},$$

where the multiplication is given by the ordinary one for monomials of z , while the addition \oplus is given by the *tropical sum*

$$(5.3) \quad \left(\prod_{i=1}^n z_i^{a_i} \right) \oplus \left(\prod_{i=1}^n z_i^{b_i} \right) = \prod_{i=1}^n z_i^{\min(a_i, b_i)}.$$

We call it the *tropical semifield of z* .

There is a semifield homomorphism

$$(5.4) \quad \begin{array}{ccc} \pi_{\text{trop}} : \mathbb{Q}_+(z) & \rightarrow & \text{Trop}(z) \\ & z_i \mapsto & z_i, \end{array}$$

which we call the *tropicalization map*.

5.2. Periodicity of seeds. Let $y = (y_1, \dots, y_n)$ be an n -tuple of formal commutative variables. We consider a sequence of seed mutations *with coefficients in the universal semifield $\mathbb{Q}_+(y)$* ,

$$(5.5) \quad (B, x, y) = (B[0], x[0], y[0]) \xrightarrow{\mu_{k_0}} (B[1], x[1], y[1]) \xrightarrow{\mu_{k_1}} \dots \\ \dots \xrightarrow{\mu_{k_{T-1}}} (B[T], x[T], y[T]).$$

Note that the initial y -variables y are set to be the generators y of $\mathbb{Q}_+(y)$.

We introduce a discrete time variable $s = 0, 1, \dots$

By applying the tropicalization map π_{trop} in (5.4) to each y -variable $y_i[s]$, ($s = 0, \dots, T$) in the sequence (5.5), we obtain a monomial of initial y -variables y ,

$$(5.6) \quad \pi_{\text{trop}}(y_i[s]) = \prod_{j=1}^n y_j^{c_{ji}[s]}.$$

The integer vector $c_i[s] = (c_{ji})_{j=1}^n$ is called the *c-vector* of $y_i[s]$.

The following fact is of fundamental importance in the theory of cluster algebras.

Theorem 5.2 ((Sign-coherence of c -vectors), [DWZ10, Theorem 1.7] with [FZ07, Proposition 5.6], [GHKK14, Corollary 5.5]). *Each c -vector is a nonzero vector, and its components are either all nonnegative or all nonpositive.*

Based on this theorem, we define the following notion.

Definition 5.3. The *tropical sign* $\varepsilon = \varepsilon(y_i[s])$ of $y_i[s]$ is given by $+$ (resp. $-$) if the components of the c -vector of $y_i[s]$ are all nonnegative (resp. nonpositive).

We introduce a sequence of signs, $\varepsilon_0, \dots, \varepsilon_{T-1}$, where

$$(5.7) \quad \varepsilon_s = \varepsilon(y_{k_s}[s]), \quad (s = 0, \dots, T-1),$$

and k_s is the one in (5.5). We call it the *tropical sign sequence* of (5.5).

Next let us consider the periodicity of the sequence (5.5).

We define a (left) action of a permutation σ of $\{1, \dots, n\}$ on $\mathcal{F}^n \times \mathbb{P}^n$ for any semifield \mathbb{P} by

$$(5.8) \quad \begin{aligned} \sigma : \mathcal{F}^n \times \mathbb{P}^n &\rightarrow \mathcal{F}^n \times \mathbb{P}^n \\ (x, y) &\mapsto (x', y'), \end{aligned}$$

$$(5.9) \quad x'_i = x_{\sigma^{-1}(i)},$$

$$(5.10) \quad y'_i = y_{\sigma^{-1}(i)}.$$

Definition 5.4. Let σ be a permutation of $\{1, \dots, n\}$. We say that a sequence of mutations (5.5) is σ -periodic if the following condition holds for any $1 \leq i, j \leq n$:

$$(5.11) \quad b_{\sigma^{-1}(i)\sigma^{-1}(j)}[T] = b_{ij}[0],$$

$$(5.12) \quad x_{\sigma^{-1}(i)}[T] = x_i[0],$$

$$(5.13) \quad y_{\sigma^{-1}(i)}[T] = y_i[0].$$

In other words, the following equality holds on $\mathcal{F}^n \times \mathbb{P}^n$:

$$(5.14) \quad \sigma \circ \mu_{k_{T-1}}^{B[T-1]} \cdots \circ \mu_{k_1}^{B[1]} \circ \mu_{k_0}^{B[0]} = \text{id}.$$

The periodicity of the seed mutations imply the periodicity of the tropical transformations, if we set the signs therein to be the tropical sign sequence.

Proposition 5.5 (Tropical periodicity for x - and y -variables). *Suppose that the sequence of mutations (5.5) is σ -periodic. Let $\tau_{k,\varepsilon}^B$ and σ be the ones in (2.12) and (5.8), respectively, for any semifield \mathbb{P} . Let $\varepsilon_0, \dots, \varepsilon_{T-1}$ be the tropical sign sequence in (5.7). Then, the following periodicity holds on $\mathcal{F}^n \times \mathbb{P}^n$:*

$$(5.15) \quad \sigma \circ \tau_{k_{T-1}, \varepsilon_{T-1}}^{B[T-1]} \cdots \circ \tau_{k_1, \varepsilon_1}^{B[1]} \circ \tau_{k_0, \varepsilon_0}^{B[0]} = \text{id}.$$

Proof. By [NZ12, Proposition 1.3] and Theorem 5.2, the sequence of transformations on the left hand side of (5.15) is the exponential form of the transformations of the corresponding c - and g -vectors along the sequence (5.5), where g -vectors are defined in [FZ07, Section 6]. Thus, the claim reduces to the σ -periodicity of c - and g -vectors along the sequence (5.5). The σ -periodicity of c -vectors directly follows from the σ -periodicity of y -variables (5.13) by applying the tropicalization map in (5.4). Then, the σ -periodicity of g -vectors follows from the duality of c - and g -vectors in [NZ12, Theorem 1.2]. \square

As a corollary of Proposition 5.5 one can also obtain the tropical periodicity of the canonical variables (u, p) . Let us define an action of a permutation σ on \mathbb{R}^{2n}

$$(5.16) \quad \begin{aligned} \sigma : \mathbb{R}^{2n} &\rightarrow \mathbb{R}^{2n} \\ (u, p) &\mapsto (u', p'), \end{aligned}$$

$$(5.17) \quad u'_i = u_{\sigma^{-1}(i)},$$

$$(5.18) \quad p'_i = p_{\sigma^{-1}(i)}.$$

Since the map σ is a canonical transformation, we may regard it as a change of canonical coordinates on the phase space M .

Corollary 5.6 (Tropical periodicity for canonical variables). *Suppose that the sequence of mutations (5.5) is σ -periodic. Let $\tau_{k,\varepsilon}^B$ and σ be the ones in (3.32) and (5.16), respectively. Let $\varepsilon_0, \dots, \varepsilon_{T-1}$ be the tropical sign sequence in (5.7). Then, the following periodicity holds on \mathbb{R}^{2n} :*

$$(5.19) \quad \sigma \circ \tau_{k_{T-1}, \varepsilon_{T-1}}^{B[T-1]} \cdots \circ \tau_{k_1, \varepsilon_1}^{B[1]} \circ \tau_{k_0, \varepsilon_0}^{B[0]} = \text{id}.$$

Proof. Since (3.33) is a log-version of (2.13), the σ -periodicity of u -variables follows from the σ -periodicity of x -variables in Proposition 5.5. Then, the σ -periodicity of p -variables follows from Proposition 3.9 (1). \square

Later we also use the following fact:

Proposition 5.7 ([Nak16, Proposition 4.3]). *Let $D = \text{diag}(d_1, \dots, d_n)$ be any common skew-symmetrizer of $B[s]$ ($s = 0, \dots, T-1$). Suppose that the sequence of mutations (5.5) is σ -periodic. Then, the following equality holds:*

$$(5.20) \quad d_{\sigma(i)} = d_i.$$

5.3. Periodicity of canonical variables. Let $\varepsilon_0, \dots, \varepsilon_{T-1}$ continue to be the tropical sign sequence of (5.5). Let $(u[0], p[0])$ be an arbitrary point in \mathbb{R}^{2n} . In parallel to the sequence of mutations (5.5), we consider a sequence of signed mutations on \mathbb{R}^{2n} ,

$$(5.21) \quad (u[0], p[0]) \xrightarrow{\mu_{k_0, \varepsilon_0}^{B[0]}} (u[1], p[1]) \xrightarrow{\mu_{k_1, \varepsilon_1}^{B[1]}} \cdots \xrightarrow{\mu_{k_{T-1}, \varepsilon_{T-1}}^{B[T-1]}} (u[T], p[T]),$$

where

$$(5.22) \quad \mu_{k_s, \varepsilon_s}^{B[s]} = \tau_{k_s, \varepsilon_s}^{B[s]} \circ \rho_{k_s, \varepsilon_s}^{B[s]}, \quad (s = 0, \dots, T-1),$$

and $\rho_{k_s, \varepsilon_s}^{B[s]}$ are defined by (3.46) under the following assumption:

Assumption 5.8. We employ a common skew-symmetrizer D of $B[s]$'s to define $\rho_{k_s, \varepsilon_s}^{B[s]}$.

Definition 5.9. Let σ be a permutation of $\{1, \dots, n\}$. We say that a sequence of signed mutations (5.21) is σ -periodic if the following condition holds for any initial point $(u[0], p[0]) \in \mathbb{R}^{2n}$ and for any $1 \leq i \leq n$:

$$(5.23) \quad u_{\sigma^{-1}(i)}[T] = u_i[0],$$

$$(5.24) \quad p_{\sigma^{-1}(i)}[T] = p_i[0].$$

In other words, the following equality holds on \mathbb{R}^{2n} :

$$(5.25) \quad \sigma \circ \mu_{k_{T-1}, \varepsilon_{T-1}}^{B[T-1]} \cdots \circ \mu_{k_1, \varepsilon_1}^{B[1]} \circ \mu_{k_0, \varepsilon_0}^{B[0]} = \text{id}.$$

Theorem 5.10 (Periodicity of canonical variables). *Suppose that the sequence of mutations (5.5) is σ -periodic. Then, the sequence of signed mutations (5.21) is also σ -periodic.*

A proof will be given in the next subsection.

Example 5.11. The inversion relation (2.5) is the simplest example of σ -periodic sequence of mutations (5.5) with $T = 2$, $k_1 = k_2 = k$, $\sigma = \text{id}$, and the tropical sign sequence is $\varepsilon_1 = +$, $\varepsilon_2 = -$. The corresponding σ -periodic sequence of signed mutations is the inversion relation (3.53) with $\varepsilon = +$.

We have a conjecture which states that the tropical part determines the non-tropical part. This is parallel to the one for the seed mutation. See, e.g., [Nak11b, Theorem 2.6] and the remark after it.

Conjecture 5.12. *The sequence of signed mutations (5.21) is σ -periodic if and only if the tropical periodicity (5.19) holds.*

5.4. Proof of Theorem 5.10.

5.4.1. *Hamiltonian point of view.* In our proof of Theorem 5.10, keeping the Hamiltonian point of view in mind is very useful. To make the presentation simple, we consider the case $T = 2$ in (5.5). Although this is a toy example, it fully contains the idea of the proof for the general case. To lighten the notation, let us abbreviate the flow in the left hand side of the sequence (5.25) as

$$(5.26) \quad (u, p) \xrightarrow{\mu} (u', p') \xrightarrow{\mu'} (u'', p'') \xrightarrow{\sigma} (u''', p''').$$

Using the decomposition (5.22) with a similar abbreviation, we write it in the following way:

$$(5.27) \quad \begin{array}{ccccc} & & (\tilde{u}', \tilde{p}') & \xrightarrow{\tau'} & (u'', p'') & \xrightarrow{\sigma} & (u''', p''') \\ & & \uparrow \rho' & & & & \\ (\tilde{u}, \tilde{p}) & \xrightarrow{\tau} & (u', p') & & & & \\ \uparrow \rho & & & & & & \\ (u, p) & & & & & & \end{array}$$

From the Hamiltonian point of view, the vertical maps ρ and ρ' are Hamiltonian flows from $t = 0$ to 1 and from $t = 1$ to 2 in the phase space M , respectively, while the horizontal maps τ , τ' , σ are changes of canonical coordinates of M so that points do not move in M . Let us gather the piecewise Hamiltonian flow from $t = 0$ to 2 in the initial chart. This can be done by the pull-back along the horizontal

arrows as follows:

$$(5.28) \quad \begin{array}{ccccc} (\tilde{u}, \tilde{p}) & \xrightarrow{\tau} & (\tilde{u}', \tilde{p}') & \xrightarrow{\tau'} & (u'', p'') & \xrightarrow{\sigma} & (u''', p''') \\ \uparrow & & \uparrow & & & & \\ \perp & & \rho' & & & & \\ (\tilde{u}, \tilde{p}) & \xrightarrow{\tau} & (u', p') & & & & \\ \uparrow & & & & & & \\ \rho & & & & & & \\ (u, p) & & & & & & \end{array}$$

Theorem 5.10 states that the points (u, p) and (u''', p''') coincide, but this coincidence happens in different charts. On the other hand, the tropical periodicity in Corollary 5.6 means that

$$(5.29) \quad \sigma \circ \tau' \circ \tau = \text{id}.$$

Thus, we have

$$(5.30) \quad (\tilde{u}, \tilde{p}) = (u''', p''').$$

Therefore, the claim of Theorem (5.10) is equivalent to the equality in the initial chart,

$$(5.31) \quad (\tilde{u}, \tilde{p}) = (u, p).$$

In other words, *the flow is periodic in the phase space M* . We will show this separately for u - and p -variables.

5.4.2. *Periodicity of p -variables.* We start on p -variables. Consider

$$(5.32) \quad \begin{aligned} \Delta p &:= \tilde{p} - p = (\tilde{p} - \tilde{p}') + (\tilde{p}' - p) \\ &= \tau^{-1}(\tilde{p}' - p') + (\tilde{p}' - p). \end{aligned}$$

By (3.23), we have

$$(5.33) \quad \tilde{p}_i - p_i = -\frac{1}{2d_i} b_{ki} \log(1 + y_k^\varepsilon),$$

$$(5.34) \quad \tilde{p}'_i - p'_i = -\frac{1}{2d_i} b'_{k'i} \log(1 + y'_{k'}{}^{\varepsilon'}),$$

where we keep the same system of abbreviation. Recall that y -variables here are defined by

$$(5.35) \quad y_i = e^{d_i p_i + w_i}, \quad y'_i = e^{d_i p'_i + w'_i},$$

and they obey the mutation rule (3.52). In particular, it is uniquely determined by the initial y -variables y_i .

Our goal is to show that $\Delta p = 0$. For this purpose, we compare the above flow of p -variables with the (logarithm of) y -variables in the sequence of mutations (5.5).

In the same spirit of (5.28) we write a diagram for the sequence (5.5),

$$(5.36) \quad \begin{array}{ccccc} (\tilde{x}, \tilde{y}) & \xrightarrow{\tau} & (\tilde{x}', \tilde{y}') & \xrightarrow{\tau'} & (x'', y'') & \xrightarrow{\sigma} & (x''', y''') \\ \uparrow & & \uparrow \rho' & & & & \\ (\tilde{x}, \tilde{y}) & \xrightarrow{\tau} & (x', y') & & & & \\ \uparrow \rho & & & & & & \\ (x, y) & & & & & & \end{array}$$

Let us set $v_i = \log y_i/d_i$, $v'_i = \log y'_i/d_i$, and so on. Here, $\log y_i$ ($y_i \in \mathbb{Q}_+(y)$) is a formal notation such that the multiplication in $\mathbb{Q}_+(y)$ is written additively. In this notation the linear aspect of the transformation $\tau_{k,\varepsilon}^B$ in (2.12) is more transparent. Note that we have $v_i''' = v_{\sigma^{-1}(i)}''$ thanks to Proposition 5.7. Then, we have

$$(5.37) \quad \begin{aligned} \Delta v &:= \tilde{v} - v = (\tilde{v} - \tilde{v}') + (\tilde{v}' - v) \\ &= \tau^{-1}(\tilde{v}' - v') + (\tilde{v} - v). \end{aligned}$$

By (2.11), we have

$$(5.38) \quad \tilde{v}_i - v_i = -\frac{1}{d_i} b_{ki} \log(1 + y_k^\varepsilon),$$

$$(5.39) \quad \tilde{v}'_i - v'_i = -\frac{1}{d_i} b'_{k'i} \log(1 + y_{k'}^{\varepsilon'}).$$

Let us compare them with (5.33) and (5.34). Note that the y -variables here are elements in $\mathbb{Q}_+(y)$, and they are different from the ones for (5.33) and (5.34). However, they mutate by the rule (2.3), which is the same rule as for the y -variables in (5.36). Moreover, the initial y -variables y_i in (5.5) are the generators of $\mathbb{Q}_+(y)$, which are formal (algebraically independent) variables. Therefore, one can specialize them arbitrarily in \mathbb{R}_+ , so that they exactly match the initial y -variables for (5.36). Under this specialization, we have

$$(5.40) \quad \Delta p = \frac{1}{2} \Delta v,$$

where we also used the fact that τ is a linear transformation. On the other hand, by the assumption of Theorem 5.10, we have $\Delta v = 0$. Therefore, $\Delta p = 0$ holds.

5.4.3. Periodicity of u -variables. Due to the relation (3.8), the periodicities of y - and p -variables imply the same periodicity of w -variables. Therefore, when the matrix $B[0]$ is *invertible*, the periodicity of u -variables immediately follows. This reasoning, however, is not applicable when the matrix $B[0]$ is not invertible. Therefore, we prove the claim directly by comparing the mutations of u - and x -variables in a similar way to the previous case. The proof is parallel, but it requires some extra argument.

Consider

$$(5.41) \quad \begin{aligned} \Delta u &:= \tilde{u} - u = (\tilde{u} - \tilde{u}') + (\tilde{u}' - u) \\ &= \tau^{-1}(\tilde{u}' - u') + (\tilde{u} - u), \end{aligned}$$

where, by (3.22),

$$(5.42) \quad \tilde{u}_i - u_i = -\frac{1}{2}\delta_{ki} \log(1 + y_k^\varepsilon),$$

$$(5.43) \quad \tilde{u}'_i - u'_i = -\frac{1}{2}\delta_{k'i} \log(1 + y_{k'}^{\varepsilon'})$$

for the same y_i and y'_i in (5.35).

Let us compare the flow of u -variables with the (logarithm of) x -variables in the sequence of mutations (5.36). Again, let us introduce formal logarithms, $z_i = \log x_i$, $z'_i = \log x'_i$, etc., to write the multiplication in $\mathcal{F}_{\mathbb{Q}_+(y)}$ in the additive way. Then, we have

$$(5.44) \quad \begin{aligned} \Delta z &:= \tilde{z} - z = (\tilde{z} - \tilde{z}') + (\tilde{z}' - z) \\ &= \tau^{-1}(\tilde{z}' - z') + (\tilde{z} - z), \end{aligned}$$

where, by (2.10),

$$(5.45) \quad \tilde{z}_i - z_i = -\delta_{ki} \log(1 + \hat{y}_k^\varepsilon) + \delta_{ki} \log(1 \oplus y_k^\varepsilon),$$

$$(5.46) \quad \tilde{z}'_i - z'_i = -\delta_{k'i} \log(1 + \hat{y}_{k'}^{\varepsilon'}) + \delta_{k'i} \log(1 \oplus y_{k'}^{\varepsilon'}).$$

It follows that we have the following expression of Δz ,

$$(5.47) \quad \Delta z = -\log f(\hat{y}) + \log f(y),$$

where $f(y) \in \mathbb{Q}_+(y)$ is a rational function of the initial y -variables y , and $f(\hat{y}) \in \mathcal{F}_{\mathbb{Q}_+(y)}$ is the one obtained from $f(y)$ by replacing y with the initial \hat{y} -variables \hat{y} and also replacing the addition in $\mathbb{Q}_+(y)$ with the one in $\mathcal{F}_{\mathbb{Q}_+(y)}$. In the same way as (5.40), we have

$$(5.48) \quad \Delta u = \frac{1}{2} \log f(y),$$

under some specialization of y in the right hand side.

Now we set $\Delta z = 0$ by the assumption of the periodicity of x -variables. This is equivalent to the equality $f(y) = f(\hat{y})$ as elements of $\mathcal{F}_{\mathbb{Q}_+(y)}$. We first claim that $f(y)$ is a *Laurent monomial* in y , possibly with some coefficients in \mathbb{Q}_+ . In fact, if $f(y)$ is not a Laurent monomial, then it includes the addition in $\mathbb{Q}_+(y)$. It follows that $f(\hat{y})$ includes the addition in $\mathcal{F}_{\mathbb{Q}_+(y)}$. However, the addition in $\mathcal{F}_{\mathbb{Q}_+(y)}$ is an operation outside of $\mathbb{Q}_+(y)$. Thus, $f(\hat{y})$ is not an element in $\mathbb{Q}_+(y) \subset \mathcal{F}_{\mathbb{Q}_+(y)}$. In particular, the equality $f(y) = f(\hat{y})$ could never occur. We next claim that actually we have

$$(5.49) \quad f(y) = 1.$$

To see it, we consider the limit $y_i \rightarrow 0$ for all i . Then, thanks to the definition of the tropical sign, we have $y_k^\varepsilon, y_{k'}^{\varepsilon'} \rightarrow 0$. Thus, by (5.44)–(5.47), we have $\log f(y) \rightarrow 0$. Therefore, $f(y)=1$. Thus, we conclude that $\Delta z = 0$ by (5.48).

This completes the proof of Theorem 5.10.

6. DILOGARITHM IDENTITIES AND ACTION INTEGRAL

6.1. Dilogarithm identities. The following theorem was proved in [Nak11b] by a cluster algebraic method with the help of the *constancy condition* from [FS95]. See also [Nak16].

FIGURE 1. Schematic diagram of a Hamiltonian flow for $T = 2$, where for simplicity we use the same abbreviation as in (5.27).

Theorem 6.1 (Dilogarithm identity [Nak11b, Theorems 6.4 and 6.8]). *Suppose that the sequence of mutations (5.5) is σ -periodic. Let $\varepsilon_0, \dots, \varepsilon_{T-1}$ be the tropical sign sequence of (5.5). Let $D = \text{diag}(d_1, \dots, d_n)$ be any skew-symmetrizer of the initial matrix B in (5.5). Then, the following identity of the Rogers dilogarithm $\tilde{L}(x)$ in (2.26) holds:*

$$(6.1) \quad \sum_{s=0}^{T-1} \frac{\varepsilon_s}{d_{k_s}} \tilde{L}(y_{k_s}^{\varepsilon_s}[s]) = 0,$$

where $y_{k_s}[s]$ are evaluated by any semifield homomorphism

$$(6.2) \quad \text{ev} : \mathbb{Q}_+(y) \rightarrow \mathbb{R}_+.$$

Below, we give an alternative proof of a slightly weaker version of the theorem, based on the Hamiltonian/Lagrangian picture presented in the current paper.

6.2. Action integral. We consider the sequence of signed mutations (5.21).

For each time span $[s, s+1]$ ($s = 0, \dots, T-1$), we have the Hamiltonian

$$(6.3) \quad H[s] = \frac{\varepsilon_s}{2d_k} \text{Li}_2(-y_{k_s}[s]^{\varepsilon_s}) \quad \text{for } [s, s+1]$$

in the s -th canonical coordinates $(u[s], p[s])$. A Hamiltonian flow from time 0 to T is a piecewise linear movement. A schematic diagram of a Hamiltonian flow is depicted in Figure 1 for $T = 2$. Let

$$(6.4) \quad \mathcal{L}[s] = \dot{u}_{k_s}[s] p_{k_s}[s] - H[s] \quad \text{for } [s, s+1]$$

be the corresponding singular Lagrangian from (4.7).

Let us consider the action integral S along a Hamiltonian flow,

$$(6.5) \quad S = \sum_{s=0}^{T-1} S[s],$$

$$(6.6) \quad S[s] = \int_s^{s+1} \mathcal{L}[s](u(t), \dot{u}(t)) dt,$$

where $u(t)$ in (6.6) is (the u -part of) a Hamiltonian flow in the s -th coordinates $(u[s], p[s])$.

Here is the first key observation.

Proposition 6.2. *The value of the Lagrangian (6.4) along a Hamiltonian flow is constant in t in each time span $[s, s+1]$. Thus, we have*

$$(6.7) \quad S = \sum_{s=0}^{T-1} \mathcal{L}[s].$$

Proof. Since the Hamiltonian is constant along the flow, it is enough to show that the term $\dot{u}_{k_s}[s]p_{k_s}[s]$ is constant. This is true since we have $\ddot{u}_{k_s}[s] = \dot{p}_{k_s}[s] = 0$ by Proposition 3.4. \square

6.3. Invariance of action integral. Our next key observation is as follows.

Theorem 6.3. *Suppose that the sequence of signed mutations (5.21) is σ -periodic. Then, for any Hamiltonian flow,*

$$(6.8) \quad S = 0.$$

The rest of this subsection is devoted to a proof of this theorem.

First we show that the value $S = S(u)$ is independent of a Hamiltonian flow $u(t)$, using the standard variational calculus for a Lagrangian. However, we have to be careful because the Lagrangian here is singular as discussed in Section 4.2.

For a given Hamiltonian flow $u(t)$, we consider an infinitesimal variation $u(t) + \delta u(t)$, which is also assumed to be a Hamiltonian flow. Let

$$(6.9) \quad \delta S[s] := S[s](u + \delta u) - S[s](u).$$

be the variation of the action integral $S[s]$ in the time span $[s, s+1]$. We show that it is given by the boundary values of the time span as follows.

Lemma 6.4.

$$(6.10) \quad \delta S[s] = \sum_{i=1}^n \tilde{p}_i[s] \delta \tilde{u}_i[s] - \sum_{i=1}^n p_i[s] \delta u_i[s],$$

where $(u[s], p[s])$ and $(\tilde{u}[s], \tilde{p}[s])$ are the points of the flow at $t = s$ and $s+1$, respectively, in the s -th coordinates $(u[s], p[s])$.

Proof. We fix the discrete time s . For simplicity, we suppress the index s everywhere, in particular we write k instead of k_s . Recall that, by Proposition 3.4, for $i \neq k$,

$$(6.11) \quad \dot{u}_i = 0.$$

Thus, we have, for $i \neq k$,

$$(6.12) \quad \delta \dot{u}_i = 0.$$

Therefore, it is natural to separate the variation $\delta S = \delta S[s]$ into two parts:

$$(6.13) \quad \delta S = \delta S_1 + \delta S_2,$$

$$(6.14) \quad \delta S_1 = \int_s^{s+1} \left(\frac{\partial \mathcal{L}}{\partial u_k} \delta u_k + \frac{\partial \mathcal{L}}{\partial \dot{u}_k} \delta \dot{u}_k \right) dt,$$

$$(6.15) \quad \delta S_2 = \sum_{\substack{i=1 \\ i \neq k}}^n \int_s^{s+1} \left(\frac{\partial \mathcal{L}}{\partial u_i} \delta u_i \right) dt.$$

Recall that by Proposition 4.3 (1) the Euler-Lagrange equation for $i = k$ follows from the equations of motion. By using it and also (4.4), we have

$$(6.16) \quad \delta S_1 = \int_s^{s+1} \left(\frac{d}{dt} \left(\frac{\partial \mathcal{L}}{\partial \dot{u}_k} \right) \delta u_k + \frac{\partial \mathcal{L}}{\partial \dot{u}_k} \delta \dot{u}_k \right) dt = \left[\frac{\partial \mathcal{L}}{\partial \dot{u}_k} \delta u_k \right]_s^{s+1} = [p_k \delta u_k]_s^{s+1}.$$

On the other hand, for $i \neq k$, by (4.15) we have an explicit expression for $\partial \mathcal{L} / \partial u_i$ and (6.11) shows δu_i is independent of t . Combining with (3.25) gives

$$(6.17) \quad \delta S_2 = \sum_{\substack{i=1 \\ i \neq k}}^n (-1) \frac{b_{ki}}{2d_i} \log(1 + y_k^\varepsilon) \delta u_i = \sum_{\substack{i=1 \\ i \neq k}}^n (\tilde{p}_i - p_i) \delta u_i.$$

(Note that in (6.17) we did not use the Euler-Lagrange equations for $i \neq k$, which are not valid here as noted after Proposition 4.3.) Recall from (3.21) that $(\tilde{u}[s], \tilde{p}[s])$ is obtained from $(u[s], p[s])$ by the time one flow of the Hamiltonian $H[s]$. Thus gathering (6.16) with (6.17) and noting that $\delta u_i = \delta \tilde{u}_i$ for $i \neq k$, we obtain (6.10). \square

Let σ be the one in (5.16), and let us introduce

$$(6.18) \quad (u[T+1], p[T+1]) := \sigma(u[T], p[T]).$$

Lemma 6.5. *We have the equalities*

$$(6.19) \quad \sum_{i=1}^n p_i[s+1] \delta u_i[s+1] = \sum_{i=1}^n \tilde{p}_i[s] \delta \tilde{u}_i[s], \quad (s = 0, \dots, T-1),$$

$$(6.20) \quad \sum_{i=1}^n p_i[T+1] \delta u_i[T+1] = \sum_{i=1}^n p_i[T] \delta u_i[T].$$

Proof. The first equality is due to Proposition 3.9 (1). The second equality is clear from the definition of σ . \square

Consider the total variation

$$(6.21) \quad \delta S = \sum_{s=0}^{T-1} \delta S[s].$$

Combining Lemmas 6.4 and 6.5, we see that it is given by the boundary values,

$$(6.22) \quad \delta S = \sum_{i=1}^n p_i[T+1] \delta u_i[T+1] - \sum_{i=1}^n p_i[0] \delta u_i[0].$$

On the other hand, by the assumption of the σ -periodicity of the sequence of signed mutations (5.21), we have

$$(6.23) \quad p_i[T+1] = p_i[0], \quad \delta u_i[T+1] = \delta u_i[0].$$

Therefore, we conclude that

$$(6.24) \quad \delta S = 0.$$

Since this holds for any infinitesimal variation of any flow $u(t)$, S is constant.

It remains to determine the constant value of S . We evaluate it in the limit $p_i[0] \rightarrow -\infty$ for all i . Then, all initial y -variables $y_i[0] = \exp(d_i p_i[0] + w_i[0])$ go to 0. Accordingly, all $y_{k_s}[s]^{\varepsilon_s}$ ($s = 0, \dots, T-1$) also go to 0 due to the definition of the tropical sign ε_s . So, by (4.9), the Lagrangians $\mathcal{L}[s]$ go to 0 as well. Thus, we have $S \rightarrow 0$. Therefore, $S = 0$.

This completes the proof of Theorem 6.3.

Remark 6.6. The meaning of Theorem 6.3 and its proof becomes more transparent if we compare them with *Noether's theorem* (e.g., [Tak08, Theorem 1.3]).

For simplicity, let us consider the variation of a general regular Lagrangian \mathcal{L} under an infinitesimal transformation $u_i \mapsto u_i + \epsilon a_i$ for some i , where ϵ is an infinitesimal and a_i is a function of u . Then, by the Euler-Lagrange equation for i , we have

$$(6.25) \quad \delta \mathcal{L} = \frac{d}{dt} \left(\frac{\partial \mathcal{L}}{\partial \dot{u}_i} \right) \epsilon a_i + \frac{\partial \mathcal{L}}{\partial \dot{u}_i} \epsilon \dot{a}_i = \epsilon \frac{d}{dt} (p_i a_i).$$

Thus, $\delta \mathcal{L} = 0$, i.e., the invariance of the Lagrangian in the order of ϵ , implies that the generator $X = p_i a_i$ is an integral of motion; that is Noether's theorem. Moreover, we see in (6.25) that the converse is also true, namely, if $X = p_i a_i$ is an integral of motion, then $\delta \mathcal{L} = 0$.

Next we consider a finite time analogue of the above. Namely, we consider a variation of the action integral S under an infinitesimal transformation of Hamiltonian flows $u_i(t) \mapsto u_i(t) + \epsilon a_i(t)$ for some i , where ϵ is an infinitesimal and $a_i(t)$ depends on $u(t)$. Then, again by the Euler-Lagrange equation, we have

$$(6.26) \quad \delta S = \int_{t_0}^{t_1} \left(\frac{d}{dt} \left(\frac{\partial \mathcal{L}}{\partial \dot{u}_i} \right) \epsilon a_i + \frac{\partial \mathcal{L}}{\partial \dot{u}_i} \epsilon \dot{a}_i \right) dt = \epsilon [p_i a_i]_{t_0}^{t_1}.$$

Thus, $\delta S = 0$, i.e., the invariance of the action integral in the order of ϵ , implies that the generator $X = p_i a_i$ is periodic at t_0 and t_1 , and *vice versa*.

6.4. Main results. By combining Propositions 4.4 and 6.2 with Theorem 6.3, we have the following theorem.

Theorem 6.7. *Suppose that the sequence of signed mutations (5.21) is σ -periodic. Then, for the Hamiltonian flow of the Hamiltonian in (6.3) with any initial point in the phase space M , we have*

$$(6.27) \quad \sum_{s=0}^{T-1} \mathcal{L}[s] = 0.$$

In particular, if the initial point $(u[0], p[0])$ in (5.21) satisfies the condition

$$(6.28) \quad d_i p_i[0] = w_i[0], \quad (i = 1, \dots, n),$$

we have the following identity of the Rogers dilogarithm $\tilde{L}(x)$ in (2.26):

$$(6.29) \quad \sum_{s=0}^{T-1} \frac{\varepsilon_s}{d_{k_s}} \tilde{L}(\hat{y}_{k_s}^{\varepsilon_s}[s]) = 0,$$

where

$$(6.30) \quad \hat{y}_i[s] = e^{2w_i[s]}.$$

Finally, by combining Theorems 5.10 and 6.7, we obtain a slightly weaker version of Theorem 6.1.

Theorem 6.8. *Suppose that the sequence of mutations (5.5) is σ -periodic. Let $\varepsilon_0, \dots, \varepsilon_{T-1}$ be the tropical sign sequence of (5.5). Let $D = \text{diag}(d_1, \dots, d_n)$ be any skew-symmetrizer of the initial matrix B in (5.5). We set the y -variables in (5.5) to be trivial by the specialization $\mathbb{Q}_+(y) \rightarrow \mathbf{1}$. Let $\mathbb{Q}_+(x) \subset \mathcal{F}$ be a semifield generated by the initial x -variables in (5.5). Then, the following identity for the Rogers dilogarithm $\tilde{L}(x)$ in (2.26) holds:*

$$(6.31) \quad \sum_{s=0}^{T-1} \frac{\varepsilon_s}{d_{k_s}} \tilde{L}(\hat{y}_{k_s}^{\varepsilon_s}[s]) = 0,$$

where

$$(6.32) \quad \hat{y}_i[s] = \prod_{j=1}^n x_j[s]^{b_{ji}[s]}$$

are evaluated by any semifield homomorphism

$$(6.33) \quad \text{ev} : \mathbb{Q}_+(x) \rightarrow \mathbb{R}_+.$$

Remark 6.9. Theorem 6.8 is apparently weaker than Theorem 6.1 because the semifield homomorphism $\mathbb{Q}_+(y) \rightarrow \mathbb{Q}_+(x)$, defined by $y_i \mapsto \hat{y}_i := \prod_{j=1}^n x_j^{b_{ji}}$ is not an isomorphism, in general. However, one can recover Theorem 6.1 from Theorem 6.8 in the following cases:

(1). Suppose that the initial matrix B in (5.5) is *invertible*. Then, the above semifield homomorphism is an isomorphism. Thus, Theorem 6.1 for such B follows from Theorem 6.8.

(2). Suppose that the initial matrix B in (5.5) is *skew-symmetric*. Then, the matrix B can be extended to an *invertible* skew-symmetric matrix \tilde{B} . It is known that, if the sequence (5.5) is σ -periodic, the sequence (5.5) with B being replaced by \tilde{B} is still σ -periodic [Nak11b, Theorem 4.3]. By (1), we obtain Theorem 6.1 for \tilde{B} from Theorem 6.8. Since the identities (6.1) for B and \tilde{B} are the same, Theorem 6.1 for B also follows.

Moreover, we conjecture that Theorem 4.3 in [Nak11b] is extended to any *skew-symmetrizable* matrix B and its skew-symmetrizable extension \tilde{B} . Under the conjecture, one can fully recover Theorem 6.1 from Theorem 6.8.
